Dijkstra's Algorithm

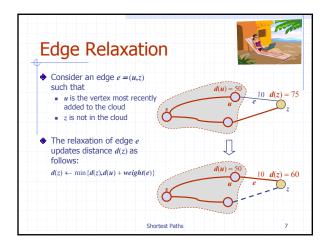

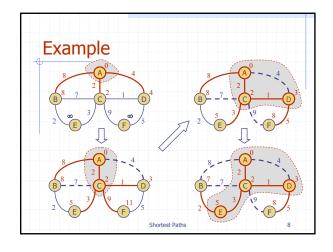

- The distance of a vertex ν from a vertex s is the length of a shortest path between s and ν
- Dijkstra's algorithm computes the distances of all the vertices from a given start vertex s
- Assumptions:
 - the graph is connected
 - the edges are undirected
 - the edge weights are nonnegative

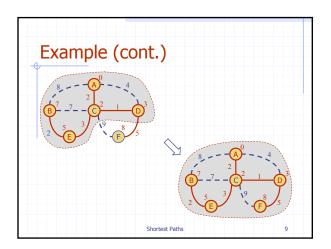

- We grow a "cloud" of vertices, beginning with s and eventually covering all the vertices
- We store with each vertex ν a label d(ν) representing the distance of ν from s in the subgraph consisting of the cloud and its adjacent vertices
- At each step
 - We add to the cloud the vertex u outside the cloud with the smallest distance label, d(u)
 - We update the labels of the vertices adjacent to u

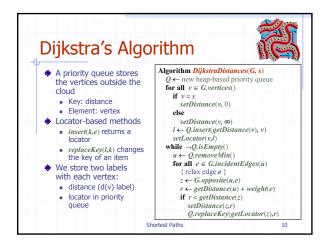

Shortest Paths

All-Pairs Shortest Paths

- Find the distance between every pair of vertices in a weighted directed graph G.

 We can make n calls to Dijkstra's algorithm (if no negative edges), which takes O(nmlog n) time.
- Likewise, n calls to Bellman-Ford would take O(n²m) time.
- We can achieve O(n³) time using dynamic programming (similar to the Floyd-Warshall algorithm).

```
Algorithm AllPair(G) {assumes vertices 1,...,n} for all vertex pairs (i,j) if i=j D_{\theta}[i,i] \leftarrow \theta else if (i,j) is an edge in G D_{\theta}[i,j] \leftarrow weight of edge (i,j) else
  \begin{split} &D_{\theta}[i,j] \leftarrow \text{rec}_{g(n)}, & \text{op} \\ &\text{else} \\ &D_{\theta}[i,j] \leftarrow + \infty \\ &\text{for } i \leftarrow l \text{ to } n \text{ do} \\ &\text{for } i \leftarrow l \text{ to } n \text{ do} \\ &\text{for } j \leftarrow l \text{ to } n \text{ do} \\ &D_{h}[i,j] \leftarrow \min\{D_{b,\cdot}[i,j], D_{b,\cdot}[i,k] + D_{b,\cdot}[k,j]\} \\ &\text{voture } D. \end{split}
```

 $\begin{array}{c|c} J_n I J_n & \dots \\ D_n & \text{Uses only vertices numbered 1,...,k} \\ \text{(compute weight of this edge)} \\ \text{vertices} & \text{Uses only vertices} \\ \text{numbered 1,...,k-1} \\ \end{array}$ Uses only vertices numbered 1,...,k-1
